

- In the `load_config()` function, you should implement a way to validate the configuration file. For example, you could check that the file exists, that it is a valid JSON file, and that it contains all of the required keys.
- In the `get_balance()` function, you should check that the address is valid before calling the `get_balance()` method on the Monero instance.
- In the `send_transaction()` function, you should handle any errors that may occur while sending the transaction. For example, you could check that the wallet has enough balance to cover the transaction fee and the amount being sent. You should also display a more informative error message to the user if the transaction fails.
